

and return in the opposite direction. The only thing that stops them is another 5/7 blemish. If two of the blemishes run headlong into one other, they cancel each other out and disappear.

### Light-Emitting Nanofibers Operate as Subwavelength and Multiple Point Sources

Light-emitting sources with constrained dimensions may play an important role in sensing and lab-on-a-chip applications operating without external optics, enhancing the sensitivity and improving the signal-to-noise ratio of detected fluorescence. J.M. Moran-Mirabal and co-workers from Cornell University produced point illumination sources based on fibers of  $[\text{Ru}(\text{bpy})_3]^{2+}$  ( $\text{PF}_6^-$ )/PEO, with electroluminescent ionic transition metal complexes (iTMCs) embedded in a polymer electrolyte on interdigitated electrodes, as reported in the February 14 issue of *Nano Letters* (p. 458, DOI: 10.1021/nl062778+).

To a solution of 50 mM ruthenium(II) tris(bipyridine) in dry acetonitrile filtered through a 450 nm polycarbonate membrane, the researchers added poly(ethylene oxide) (PEO) as the carrier polymer, whose concentration tuned the viscosity of the electrospinning solution and affected the size of the fibers with diameters ranging from 150 nm to several microns. Fibers were electrospun at 8–10 kV on silicon substrates with a 300–600 nm thermal oxide insulating layer and with micropatterned gold interdigitated electrodes (IDEs) on top, using a microfabricated tip coated with gold and keeping the tip-to-substrate distance between 25 mm and 40 mm.

Fibers deposited on a device having a 5  $\mu\text{m}$  interelectrode spacing emitted light confined to a planar region  $540 \times 540 \text{ nm}^2$  with the out-of-plane dimension limited by the thickness of the fiber when applying a dc bias across the IDEs in a dry nitrogen atmosphere. These devices showed additional emission zones as the voltage increased, resulting in multiple light sources within a fiber. This represents an advantage to develop multiple light sources in parallel, with emission sites defined by interelectrode gaps. Fibers deposited on a device with 500 nm interelectrode spacing showed a single homogeneous emission zone confined to planar regions of  $240 \times 325 \text{ nm}^2$  or smaller with the emission spectrum centered at 600 nm, which implies that these devices operate as subwavelength point sources, as well as a reduced turn-on voltage. For the electroluminescent fibers deposited on 5  $\mu\text{m}$  IDEs, emission could be detected by a CCD camera when applied voltages were

$\sim 10 \text{ V}$  and by eye in a dark room at 100 V. For the electroluminescent fibers deposited on 500 nm IDEs, emission could be detected at voltages as low as 2.6 V. Relatively long lifetimes were achieved during continuous operation at high voltages, which could be improved, in air, by encapsulation of the light-emitting fibers or substitution of the carrier polymer.

By using other ionic transition metal complexes with emission at different wavelengths in the visible spectrum, nanoscopic light-emitting sources can be produced that excite multiple fluorescent tags, enabling the full integration of excitation and detection mechanisms on lab-on-a-chip devices.

### Integrated Optical Device Fabricated from $\text{KY}(\text{WO}_4)_2$

In the March 1 issue of *Optics Letters* (p. 488), researchers from the Advanced Photonics Laboratory at the Ecole Polytechnique Fédérale de Lausanne (EPFL, Switzerland), led by M. Pollnau, have reported the fabrication of riblike waveguide structures based on  $\text{KY}(\text{WO}_4)_2$  (i.e., KYW) doped with Yb ( $\text{KYW}:\text{Yb}$ ), and codoped with  $\text{Lu}^{3+}$  and  $\text{Gd}^{3+}$ . The researchers also demonstrated the fabrication of a Y-junction with a splitting ratio close to 1:1. According to the researchers, “these riblike structures offer great potential for applications toward integrated optics on KYW.”

The researchers said that bulk KYW crystals doped with rare-earth ions are one of the most promising materials for obtaining novel solid-state lasers. In this crystal, the  $3+$  rare-earth ions can easily be incorporated, replacing the  $\text{Y}^{3+}$  ions. This results in an optically active material with high emission and absorption cross-sections for the rare-earth ions. Doping with Yb ions is of particular interest because an extremely small laser quantum defect ( $\sim 1.6\%$ ) can be achieved in  $\text{KYb}(\text{WO}_4)_2$ . The realization of waveguide structures is also of great interest for the development of integrated optical devices.

Recently, in previous work, planar Yb-doped KYW was demonstrated based on high-quality monoclinic  $\text{KYW}:\text{Yb}$  epitaxial layers grown on KYW substrates. In this case, the refractive index contrast ( $\Delta n$ ) between the active layer and the substrate was only  $\sim 6 \times 10^{-4}$ . This  $\Delta n$  is enough to demonstrate waveguide laser action but not for the development of efficient planar integrated structures with high optical confinement.

In the new work reported here, the researchers grew crack-free  $\text{KYW}:\text{Yb}$  epitaxial layers codoped with  $\text{Lu}^{3+}$  and  $\text{Gd}^{3+}$

ions. The  $\text{Lu}^{3+}$  and  $\text{Gd}^{3+}$  ions were optically inert and their role was to increase the refractive index of the active layer. The refractive index contrasts between KYW and  $\text{KLu}(\text{WO}_4)_2$  and  $\text{KLu}(\text{WO}_4)_2$  are  $\sim 2 \times 10^{-2}$  and  $\sim 1 \times 10^{-2}$ , respectively. The incorporation of different rare-earth ions in the KYW matrix leads to changes in the lattice parameter. While  $\text{Gd}^{3+}$  ions lead to compressive strains, the incorporation of  $\text{Yb}^{3+}$  and  $\text{Lu}^{3+}$  ions induces tensile strains. Therefore, by adjusting the concentration of the different rare-earth ions, it is possible to achieve an epitaxial layer characterized by a high refractive index and a low lattice-induced strain, and with large flexibility concerning the concentration of the optically active  $\text{Yb}^{3+}$  ions.

The epitaxial Lu,Gd-codoped KYW:Yb layers were grown by liquid phase epitaxy. Using concentrations of 25.3% for the Lu, 13% for the Gd, and 1.7 at % for Yb, the researchers were able to grow crack-free layers with a thickness of up to 8–10  $\mu\text{m}$  and with a  $\Delta n = 7.5 \times 10^{-3}$ . Subsequently, two-dimensional waveguide structures were fabricated using standard UV photolithography and reactive ion etching. Ribs with widths from 3  $\mu\text{m}$  to 9  $\mu\text{m}$  exhibit single mode behavior. The researchers established that the losses at the fluorescent wavelength of 1020 nm will be below 1 dB/cm for straight waveguides. In order to analyze the potential for building integrated optical devices, the researchers have designed and produced a Y-splitter with a splitting ratio of 1:1 and additional losses of 1.4 dB.

### Nanoelectrodes Probe Microscale Environments

Investigating the composition and behavior of microscale environments, including those within living cells, could become easier and more precise with nanoelectrodes being developed at the University of Illinois at Urbana-Champaign (UIUC).

“The individual nanotube-based probes can be used for electrochemical and biochemical sensing,” said M.-F. Yu, a professor of mechanical science and engineering at UIUC, and a researcher at the university’s Beckman Institute. “The position of the nanoelectrodes can be controlled very accurately.”

To fabricate the nanoelectrodes, Yu and graduate students K. Yum, J. Hu, and H.N. Cho begin by attaching a strong, rigid, boron-nitride nanotube to a much larger, conductive probe. The nanotube will form the insulating core of the nanoelectrode.

The researchers then coat the nanotube with a thin film of gold  $\sim 10$ –50 nm thick.

The gold layer is coated with an insulating polymer coating ~10 nm thick. The researchers use a focused ion beam to slice off the end of the nanotube, exposing a conducting ring of gold sandwiched between an insulating core and an insulating outer ring.

The process yields nanoelectrodes with a diameter of 100 nm, and a length of up to 30  $\mu\text{m}$ .

Because the nanotube is attached to a much larger probe, the researchers can

manipulate the nanotube like a needle. They can control precisely where the nanotube penetrates a cell, for example, and even pinpoint smaller cell structures, such as the nucleus or mitochondrion.

"Nanoelectrodes offer new opportunities for electrochemical sensing in intracellular environments," said Yu, who was scheduled to describe the fabrication process and demonstrate the feasibility of nanoelectrodes at the meeting of the American Physical Society held in

Denver in March. "By functionalizing the active area of the nanoelectrode with an appropriate chemical, we can target the detection of specific chemical species."

The researchers have demonstrated that their nanoelectrode can sense the chemical environment within a droplet 10  $\mu\text{m}$  in diameter. Their next step is to show that the probe can penetrate the cellular membrane of a living cell, without damaging the cell.

### Patrick Bruno and Peter Gumbsch Named 2007 Leibniz Prize Recipients

Patrick Bruno of Max Planck Institute of Microstructure Physics, Halle and Peter Gumbsch of the Institute for Reliability of Components and Systems (IZBS), University of Karlsruhe, and Fraunhofer Institute for Mechanics of Materials (IWM), Freiburg and Halle have each been named recipients of Germany's most highly endowed research award, the Gottfried Wilhelm Leibniz Prize, given by the German Research Foundation (DFG). DFG has named 10 scientists and academics to receive the 2007 prize, which includes up to 2.5 million euros to be used flexibly over a period of seven years to finance their research.

Patrick Bruno's scientific interests are focused on theoretical solid-state physics, especially the theory of magnetism in low-dimensional systems and in nanostructures.

Patrick Bruno

His explanation of special exchange interactions in ferromagnetic layered systems ("interlayer exchange coupling") is already a staple of modern textbooks on solid-state physics.

Bruno analyzed several magnetic effects in quantum mechanics (e.g., Casimir effect, spin Hall effect) and examined the role of Berry phases in anisotropic ferromagnets. In doing so, he often elucidated new aspects of standard theories. The scope of his knowledge, which spans the entire field of theoretical solid-state physics, is especially evident in numerous overview articles he published about hot topics such as the spin polarization of nanostructures, quantum nanomagnets, and magnetic semiconductors.

Bruno studied physics in Saint-Cloud and Paris, where he graduated in solid-state physics in 1986. He earned his doctorate degree in Orsay in 1989. Since 1998 he has been a scientific member of the Max Planck Society and a director at the Max Planck Institute of Microstructure Physics in Halle. In 1999, he was appointed honorary professor at the Martin Luther University Halle-Wittenberg.

At the intersection of physics and engineering, Peter Gumbsch works in the field of materials science, where he specializes in the mechanics of materials. In addition to his research on deformation in thin films, he has focused particularly on the dynamics of deformation processes and the dislocations underlying deformation (irregularities in the lattice structure of solid materials) at high velocities. In a similar manner, Gumbsch has analyzed the elementary mechanisms of fracture. Using atomistic investigations and the first serious quantum-mechanical calculations of brittle fracture behavior, he expanded the thermodynamic model that had been the textbook standard with important insights into the breaking of atomic bonds. He is instrumental in the development of multiscale materials modeling, a cutting-edge discipline used to describe materials across scales, from individual atoms to crystals to complete workpieces.

After obtaining his doctorate degree in physics at the University of Stuttgart, Gumbsch went to Oxford in 1991 as visiting scientist, before returning to Stuttgart to work at the Max Planck Institute for Metals Research. He is currently tenured professor for mechanics of materials and head of the Institute for Reliability of Components and Systems at the University of Karlsruhe, as well as director of the Fraunhofer Institute for Mechanics of Materials (IWM) in Freiburg and Halle.

Peter Gumbsch

Paul Alivisatos (University of California at Berkeley and E.O. Lawrence Berkeley National Laboratory) and Mounqi Bawendi (Massachusetts Institute of Technology) have received a joint Ernest Orlando Lawrence Award for the Materials Research category and Steven Zinkle (Oak Ridge National Laboratory) received the award for the Nuclear Technology category. The award honors scientists and engineers at mid-career for exceptional contributions in research and development that support the Department of Energy and its mission to advance the national, economic, and energy security of the United States.

Siegfried S. Hecker has been appointed as co-director of the Center for International Security and Cooperation in the Freeman Spogli Institute for International Studies at Stanford University. He also assumed positions as a professor in the Stanford School of Engineering's Department of Management Science and Engineering and a senior fellow at FSI. The center, traditionally co-directed by a scientist and social scientist since its founding in 1983, draws from a range of disciplines to focus on current problems in international security.

Hsiu-Wen Wang (Indiana University, Bloomington) and Christian Long (University of Maryland) have each been awarded a Bruker AXS 2006 Excellence in X-Ray Diffraction Scholarship. Wang was honored for unique applications in the category of Geology and Chemistry; the title of her winning paper is "Dehydration/Rehydration Induced Phase Transitions in Natrolite." Long was honored for unique applications in the category of Materials Science; his paper is entitled "Rapid Structural Mapping of the Ternary Metallic Alloy Systems Using the Combinatorial Approach and Cluster Analysis." Honorary mentions went to Matt Izawa (University of Western Ontario) and Svetlana Neretina (McMaster University, Ontario). □
