

On the Structure of Cuntz Semigroups in (Possibly) Nonunital C*-algebras

Aaron Peter Tikuisis and Andrew Toms

Abstract. We examine the ranks of operators in semi-finite C^* -algebras as measured by their densely defined lower semicontinuous traces. We first prove that a unital simple C^* -algebra whose extreme tracial boundary is nonempty and finite contains positive operators of every possible rank, independent of the property of strict comparison. We then turn to nonunital simple algebras and establish criteria that imply that the Cuntz semigroup is recovered functorially from the Murray–von Neumann semigroup and the space of densely defined lower semicontinuous traces. Finally, we prove that these criteria are satisfied by not-necessarily-unital approximately subhomogeneous algebras of slow dimension growth. Combined with results of the first author, this shows that slow dimension growth coincides with \mathcal{Z} -stability for approximately subhomogeneous algebras.

1 Introduction

It has recently become apparent that the question of which ranks, suitably defined, can occur in a simple and stably finite C^* -algebra has considerable bearing on the deeper structure of the algebra. The most significant example is due to Winter, who uses the notion of approximate divisibility of ranks in such algebras as an essential ingredient in his proof of \mathbb{Z} -stability for a wide class of nuclear C^* -algebras [23]. \mathbb{Z} -stability, in turn, is by now an indispensable tool in the effort to classify simple separable amenable C^* -algebras via K-theoretic data.

Several articles have appeared concerning ranks of operators in unital C^* -algebras ([4,6,16,20]); much of that work required further assumptions on the comparability of positive operators in the sense of Cuntz. Here, we pursue two lines of research. On the one hand, we prove that a unital simple C^* -algebra with finitely many extreme tracial states contains positive operators of every possible rank, regardless of separability, nuclearity, or comparability of positive operators.

We also begin to treat the nonunital and potentially stably projectionless cases, particularly nonunital approximately subhomogeneous algebras. We define a measure (called the radius of divisibility) of how closely each linear strictly positive function on the trace space of an algebra can be approximated by the rank function of

402

a positive operator, and then show that this quantity is lower semicontinuous with respect to inductive limits. After computing this invariant for recursive subhomogeneous algebras, we are able to explicitly describe the Cuntz semigroup of simple approximately subhomogeneous algebras with slow dimension growth, à la Brown, Perera, and Toms [4]. In [22], the first author shows that this structure for the Cuntz semigroup entails \mathbb{Z} -stability of the approximately subhomogeneous algebra; in fact, slow dimension growth and \mathbb{Z} -stability are equivalent for simple approximately subhomogeneous algebras, extending the main result of [20] to the nonunital case.

Our result for unital simple C^* -algebras with finitely many extreme traces bears some relationship to the main result of [12], which says that for unital, simple, separable, nuclear C^* -algebras with finitely many extreme traces, strict comparison and \mathbb{Z} -stability are equivalent. On the one hand, their result implies ours under the additional hypotheses of separability, nuclearity, and strict comparison. In [23], one finds another \mathbb{Z} -stability theorem for C^* -algebras under a number of hypotheses, including (tracial) m-divisibility, a condition related to the ranks of positive operators. Our result gives evidence that one may not be surprised that the \mathbb{Z} -stability theorem in [12] does not have a condition about the ranks of positive operators as a hypothesis. Such a condition holds automatically for the algebras considered there.

The organization of this paper is as follows. After preliminaries in Section 2, we discuss traces and C*-algebras with compact primitive ideal space in Section 3. Our first main result, concerning C*-algebras with finitely many extreme traces, is in Section 4. The radius of divisibility and its pertinent properties are established in Section 5. Section 6 contains a computation of the Cuntz semigroup for simple exact C*-algebras, assuming that the Cuntz semigroup enjoys certain regularity properties. Finally, we apply the theory developed in Sections 5 and 6 to approximately subhomogeneous C*-algebras in Section 7.

2 Preliminaries

Let A be a \mathbb{C}^* -algebra. Let us consider on $(A \otimes \mathcal{K})_+$ the relation $a \lesssim b$ if $v_n b v_n^* \to a$ for some sequence (v_n) in $A \otimes \mathcal{K}$. Let us write $a \sim b$ if $a \lesssim b$ and $b \lesssim a$. In this case we say that a is Cuntz equivalent to b. Let $\mathbb{C}u(A)$ denote the set $(A \otimes \mathcal{K})_+/\sim$ of Cuntz equivalence classes. We use [a] to denote the class of a in $\mathbb{C}u(A)$. It is clear that $[a] \leq [b] \Leftrightarrow a \lesssim b$ defines an order on $\mathbb{C}u(A)$. We also endow $\mathbb{C}u(A)$ with an addition operation by setting [a] + [b] := [a' + b'], where a' and b' are orthogonal and Cuntz equivalent to a and b, respectively (the choice of a' and b' does not affect the Cuntz class of their sum). In addition, $\mathbb{C}u(A)$ has the relation $\mathbb{C}u(A)$ and $\mathbb{C}u(A) = \mathbb{C}u(A)$ if $\mathbb{C}u(A) = \mathbb{C}u(A)$ is an increasing sequence in $\mathbb{C}u(A)$ and $\mathbb{C}u(A) = \mathbb{C}u(A)$ for $\mathbb{C}u(A)$ and $\mathbb{C}u(A) = \mathbb{C}u(A)$ and $\mathbb{C}u(A) = \mathbb{C}u(A)$ and $\mathbb{C}u(A) = \mathbb{C}u(A)$ and $\mathbb{C}u(A) = \mathbb{C}u(A)$ be a supportant in the theory of the Cuntz semigroup, particularly since the seminal article $\mathbb{C}u(A)$

We shall use T(A) to denote the set of lower semicontinuous, densely finite (a.k.a. densely defined) traces, as defined in [13, Definition 5.2.1]. Given $\tau \in T(A)$ we define a map $d_{\tau} \colon \mathcal{C}u(A) \to [0, \infty]$ by the formula

$$d_{\tau}([a]) := \lim_{n \to \infty} \tau(a^{1/n}).$$

This is well defined. We could make this definition whenever τ is a 2-quasitrace, but we wish to avoid defining these here. Indeed, we are only concerned here with exact C^* -algebras, and all 2-quasitraces on an exact C^* -algebra are traces; this was shown in [2] by reducing to the unital case, which was proven by Haagerup [11]. All functionals on Cu(A) (suitably-defined) are of the form d_{τ} for a 2-quasitrace τ [1].

Define $\iota: (A \otimes \mathcal{K})_+ \to \mathrm{Lsc}(T(A), [0, \infty])$ by

$$\iota(a)(\tau)=d_{\tau}(a).$$

Then $\iota(a)$ is lower semicontinuous (see [16, Proposition 2.10] in the unital case, [9, Section 5.1] in general). When we ask which ranks of positive operators occur, we mean: what is the range of ι ?

We shall say that Cu(A) is almost unperforated if, whenever $[x], [y] \in Cu(A)$ satisfy $(k+1)[x] \le k[y]$ for some $k \in \mathbb{N}$, it follows that $[x] \le [y]$.

3 Compact Primitive Ideal Space and Traces

Proposition 3.1 Let A be a C*-algebra. The following statements are equivalent:

- (i) Prim(*A*) is compact;
- (ii) there exists $e \in A_+$ and $\epsilon > 0$ such that $(e \epsilon)_+$ is full;
- (iii) there exists a full element in the Pedersen ideal of A;
- (iv) there exist $a, b \in M_n(A)_+$, some n, such that a is full and $[a] \ll [b]$.

Proof The equivalence of (i) and (ii) follows directly from [19, Proposition 3.5]. (ii) \Rightarrow (iii) is clear since $(e - \epsilon)_+$ is in the Pedersen ideal of A (this is evident from the description of the Pedersen ideal in the proof of [13, Theorem 5.6.1]).

(iii) \Rightarrow (iv): Let a be full and in the Pedersen ideal. We shall show that there exists $b \in M_n(A)_+$ for some n such that $[a] \ll [b]$.

The proof of [13, Theorem 5.6.1] shows that there exist $x_1, \ldots, x_n \in A_+$ and $f_1, \ldots, f_k \in C_c((0, \infty))_+$ such that

$$a \leq \sum_{i=1}^n f_i(x_i).$$

Thus,

$$[a] \leq \sum_{i} [f_i(x_i)] \ll \sum_{i} [x_i],$$

which is to say that if

$$b:=\bigoplus_i x_i,$$

then $[a] \ll [b]$.

(iv) \Rightarrow (i): Given a, b as in (iv), there exists $\epsilon > 0$ such that $[a] \ll [(b - \epsilon)_+]$. In particular $a \lesssim (b - \epsilon)_+$, whence $(b - \epsilon)_+$ is full. (ii) now follows for $M_n(A)$ by setting b = e. From the equivalence of (i) and (ii) we have that $Prim(M_n(A)) \cong Prim(A)$ is compact, as required.

Remark It was pointed out by George Elliott that the equivalence of (iii) and (iv) can be generalized to the following fact: for any C*-algebra A, the Pedersen ideal of

A is

$$(3.1) \{a \in A : \exists b \in (A \otimes \mathcal{K})_+ \text{ s.t. } [a] \ll [b] \text{ in } \mathfrak{C}u(A)\}.$$

Indeed, one inclusion is evident from the proof of [13, Theorem 5.6.1], while the other is shown by proving that the set (3.1) is an ideal. This turns the equivalence of (iii) and (iv) into a more general statement (and provides an alternate proof).

Lemma 3.2 Let A be a C*-algebra. If $a \in A_+$ is full, then $\infty[a] := \sup_n n[a]$ is the largest element of Cu(A).

Proof By Brown's Theorem [3], we have $\overline{aAa} \otimes \mathcal{K} \cong A \otimes \mathcal{K}$; by identifying these, we can assume that a is strictly positive. Let (p_n) be an increasing sequence of finite rank projections converging to $\mathbf{1} \in B(\mathcal{H})$ in the strong operator topology, so that $f_n := a^{1/n} \otimes p_n$ is an approximate unit for $A \otimes \mathcal{K}$. Let $b \in (A \otimes \mathcal{K})_+$ and let $\epsilon > 0$ be given, and find $k \in \mathbb{N}$ large enough that

$$||b^{1/2}f_kb^{1/2}-b||<\epsilon.$$

It follows by [17, Proposition 2.2] that there is $x \in A \otimes \mathcal{K}$ such that

$$(xb^{1/2}) f_k(xb^{1/2})^* = (b - \epsilon)_+,$$

whence

$$\infty[a] \ge \operatorname{rank}(p_k)[a] = [f_k] \ge [(b - \epsilon)_+].$$

Since ϵ was arbitrary, we have $\infty[a] \ge [b]$, as required.

Lemma 3.3 Let A be a C*-algebra with $a \in A_+$ full. If τ is a lower semicontinuous trace on A_+ with $\tau(a) < \infty$, then τ is densely finite.

Proof It will suffice to prove that $\tau((b-\epsilon)_+) < \infty$ for each $b \in A_+$ and $\epsilon > 0$. Let b and ϵ be given. By Lemma 3.2 we have $\infty[a] \ge [b]$, so that

$$\infty[a] \gg [(b - \epsilon/2)_+].$$

It follows that $n[a] \ge [(b - \epsilon/2)_+]$ for some $n \in \mathbb{N}$, so we can find $x \in A \otimes \mathcal{K}$ such that

$$x\left(\bigoplus_{i=1}^{n}a\right)x^{*}=(b-\epsilon)_{+}.$$

Extending τ to $A \otimes \mathcal{K}$ we then have

$$\tau((b-\epsilon)_+) = \tau\left(\left(\bigoplus_{i=1}^n a^{1/2}\right)(x^*x)\left(\bigoplus_{i=1}^n a^{1/2}\right)\right)$$

$$\leq ||x||^2 \tau\left(\bigoplus_{i=1}^n a\right) < \infty.$$

For any $a \in A$, set

$$T_{a\mapsto 1}(A) := \{ \tau \in T(A) : \tau(a) = 1 \}.$$

(In the case that A is unital and a = 1, this is of course the set of normalized traces.)

Proposition 3.4 Suppose that $e \in A_+$ is full and in the Pedersen ideal of A. It follows that

- (i) $T_{e\mapsto 1}(A)$ is a base for the cone of densely finite traces on A;
- (ii) $T_{e\mapsto 1}(A)$ is compact, in the topology of pointwise converge on the Pedersen ideal of A;
- (iii) $T_{e\mapsto 1}(A)$ is a Choquet simplex.

Proof (i) Suppose $\tau \in T(A) \setminus \{0\}$. Then $\tau(e) > 0$, or else e would not be full. Also, $\tau(e) < \infty$ since e is in the Pedersen ideal. Hence $\tau \in \mathbb{R}_+ T_{e \mapsto 1}(A)$, as required.

(ii) We shall show that T(A) is closed in the topology defined in [9, Section 3.2], from which it follows that it is compact in that topology. By (i) and [9, Proposition 3.10], the restriction of this topology to $T_{e\mapsto 1}(A)$ agrees with the topology of pointwise convergence on the Pedersen ideal.

Suppose that $(\tau_i) \subseteq T_{e\mapsto 1}(A)$ is a net which converges to $\tau \in T(A)$. Since e is in the Pedersen ideal, by the proof of [13, Theorem 5.6.1], let $e \le (a - \epsilon)_+$ for some $a \in (A \otimes \mathcal{K})_+$ and $\epsilon > 0$. Since [e] is full there is $n \in \mathbb{N}$ such that $[(a - \epsilon/2)_+] \ll n[e]$; we can even arrange that $[(a - \epsilon/2)_+] \ll n[(e - \delta)_+]$ for sufficiently small δ . We can then find $\epsilon > 0$ and $x \in M_n(A)$ such that

$$e \leq (a - \epsilon)_+ = x \Big(\bigoplus_{i=1}^n (e - \delta)_+ \Big) x^*.$$

Therefore, for any $\eta \in T(A)$, we have

$$\eta(e) \le n ||x||^2 \eta((e-\delta)_+) \le K \eta((e-\delta)_+),$$

where $K = n||x||^2$. Using the definition of the topology in [9, Section 3.2], we have

$$1/K = \limsup_{i \to \infty} \tau_i(e)/K \le \tau_i((e-\delta)_+) \le \tau(e) \le \liminf_{i \to \infty} \tau_i(e) = 1.$$

Therefore, τ is a nonzero, densely finite trace on A. It follows from [9, Proposition 3.10], that since e is in the Pedersen ideal,

$$\tau(e) = \lim \tau_i(e) = 1.$$

Hence, $\tau \in T_{e \mapsto 1}(A)$ as required.

(iii) The cone of densely finite traces is, by [14, Corollary 3.3] and [15, Theorem 3.1] a lattice cone. It follows from this, (i), and (ii) that $T_{e\mapsto 1}(A)$ is a Choquet simplex.

4 C*-algebras with Finitely Many Extreme Traces

Suppose that the Pedersen ideal of *A* contains a full element *e*, which we also ask to be positive. We may clearly identify $Lsc(T(A), (0, \infty])$ with the space

$$LAff(T_{e\mapsto 1}(A), (0, \infty])$$

of lower semicontinuous affine functions $T_{e\mapsto 1}(A)$ to $(0,\infty]$.

Proposition 4.1 Suppose that A has a full positive element e in its Pedersen ideal. Then the range of ι contains all of $Lsc(T(A), (0, \infty])$ if and only if the range of ι contains a uniformly dense subset of continuous affine functions $T_{e\mapsto 1}(A) \to (0, \infty)$. Moreover, in this case, $Lsc(T(A), (0, \infty]) \subset \iota(\mathcal{C}u(A) \setminus V(A))$.

Proof The forward direction is obvious. Conversely, suppose that ι contains a uniformly dense subset of continuous affine functions as above. By [10, Theorem 11.8], every function in $Lsc(T(A), (0, \infty])$ is the supremum of continuous linear functions $T(A) \to (0, \infty)$ (strictly speaking, [10, Theorem 11.8] deals with functions whose codomain is \mathbb{R} , but the same proof works for codomain $(0, \infty]$). By [7], we may in fact obtain each function in $Lsc(T(A), (0, \infty])$ as an increasing net of continuous linear functions. Since A is separable, T(A) is metrizable and we can replace such a net by a sequence. The proof of this last statement does not quite go as one might expect, so we separate the argument as its own lemma.

Lemma 4.2 Let X be a metrizable compact Hausdorff space. Suppose that $f: X \to [0, \infty]$ is a lower semicontinuous function that is the pointwise supremum of an increasing net (f_{α}) of lower semicontinuous functions. Then f is the pointwise supremum of an increasing sequence (f_{α_i}) .

Proof Let $(q_k)_{k=1}^{\infty}$ be a dense sequence in $[0,\infty)$. For each k, $f^{-1}((q_k,\infty])$ is open, and since X is metrizable, it is σ -compact. Therefore, we can find an increasing sequence of open sets $(U_{k,i})_{i=1}^{\infty}$, each of which has compact closure, with union $f^{-1}((q_k,\infty])$; moreover, $\overline{U_{k,i}} \subseteq f^{-1}((q_k,\infty])$ for each i.

By using the compactness of $\overline{U_{k,i}}$, lower semicontinuity of each f_{α} , and the fact that the net (f_{α}) is increasing, we can find α_i such that $f_{\alpha_i}(x) > q_k$ for all $x \in \overline{U_{k,i}}$, $i = 1, \ldots, k$. This condition, together with density of $\{q_k\}$, forces f to be the pointwise supremum of (f_{α_i}) . As the net (f_{α}) is increasing, it is clear that we can arrange that (f_{α_i}) is increasing.

We now have that for $f \in Lsc(T(A), (0, \infty])$, there exists an increasing sequence (f_n) of continuous linear functions $T(A) \to (0, \infty)$ whose pointwise supremum is f. By hypothesis, let S be a uniformly dense subset of continuous affine functions from $T_{e\mapsto 1}(A)$ to $(0,\infty)$ that is contained in the range of ι . By compactness of $T_{e\mapsto 1}(A)$, let $\delta_1 \in (0,1)$ such that $f_1(\tau) > \delta_1$ for all $\tau \in T_{e\mapsto 1}(A)$. Then there exists $g_1 \in S$ such that

$$f_1(\tau) - \delta_1 < g_1(\tau) < f_1(\tau)$$

for all $\tau \in T_{e \mapsto 1}(A)$. Since $f_2(\tau) \ge f_1(\tau) > g_1(\tau)$, we may likewise pick $\delta_2 \in (0, 1/2)$ such that

$$f_2(\tau) - \delta_2 > g_1(\tau)$$

for all $\tau \in T_{e \mapsto 1}(A)$. Then there exists $g_2 \in S$ such that

$$f_2(\tau) - g_1(\tau) - \delta_2 < g_2(\tau) < f_2(\tau) - g_1(\tau)$$

for all $\tau \in T_{e \mapsto 1}(A)$. That is to say,

$$f_2 - \delta_2 < g_1 + g_2 < f_2$$
.

We may continue this process, finding a sequence of numbers $\delta_n \in (0, 1/n)$ and functions $g_n \in S$ such that

$$f_n - \delta_n < g_1 + \cdots + g_n < f_n.$$

Evidently, for all $\tau \in T_{e \mapsto 1}(A)$, we have

$$f(\tau) = \sup f_n(\tau) = \sum_{n=1}^{\infty} g_n(\tau).$$

Since $g_n \in S$, we have $g_n = \iota(a_n)$ for some $a_n \in (A \otimes \mathcal{K})_+$ with $||a_n|| < 1/2^n$. Then we have

$$\sum_{n=1}^{\infty} g_n = \iota \Big(\bigoplus_{n=1}^{\infty} a_n \Big) \,,$$

as required.

The last statement of the proposition follows, since $\left[\bigoplus_{n=1}^{\infty} a_n\right]$ is the supremum of the strictly increasing sequence $\left[\bigoplus_{n=1}^{N} a_n\right]$.

Proposition 4.3 Let A be unital such that $\partial_e T(A)$ is compact and totally disconnected. Then every continuous function $\partial_e T(A) \to (0, \infty)$ is the uniform limit of functions in the range of ι .

Proof Let $f: \partial_e T(A) \to (0, \infty)$ be a continuous function and let $\epsilon > 0$. By [6, Lemma 4.1], for each point $\tau \in \partial_e T(A)$, there exists $a_\tau \in (A \otimes \mathcal{K})_+$ and a neighbourhood U_τ of τ such that

$$|d_{\gamma}(a_{\tau}) - f(\gamma)| < \epsilon/3$$

for all $\gamma \in U_{\tau}$. By continuity of f, we may, by possibly shrinking U_{τ} , also assume that $|f(\gamma) - f(\tau)| < \epsilon/3$ for $\gamma \in U_{\tau}$. Also, by the hypothesis that $\partial_e T(A)$ is completely disconnected, we can assume that U_{τ} is closed.

By compactness of $\partial_e T(A)$, let $U_{\tau_1}, \ldots, U_{\tau_n}$ be a finite subcover. By shrinking some of the sets, we may in fact assume that $U_{\tau_1}, \ldots, U_{\tau_n}$ are pairwise disjoint.

Using [6, Lemma 4.5] with a_{τ_i} , let $b_i \in (A \otimes \mathcal{K})_+$ be such that $d_{\tau}(b_i) = a_{\tau_i}(\tau)$ for all $\tau \in U_{\tau_i}$, and

$$d_{\tau}(b_i) < \frac{\epsilon}{3(n-1)}$$

for $\tau \notin U_{\tau_i}$.

Set $a = b_1 \oplus \cdots \oplus b_n$. Then for $\tau \in \partial_e T(A)$, let i be such that $\tau \in U_{\tau_i}$. Then

$$\begin{aligned} |d_{\tau}(b) - f(\tau)| \\ &\leq \sum_{j \neq i} |d_{\tau}(b_{j})| + |d_{\tau}(b_{i}) - d_{\tau}(a_{i})| + |d_{\tau}(a_{i}) - f(\tau_{i})| + |f(\tau_{i}) - f(\tau)| \\ &< (n-1)\frac{\epsilon}{3(n-1)} + 0 + \epsilon/3 + \epsilon/3 = \epsilon, \end{aligned}$$

as required.

Corollary 4.4 If A is unital and simple and $\partial_e T(A)$ is finite, then ι is onto.

Proof This follows from Propositions 4.1 and 4.3.

The Radius of Divisibility

Abstracting the technique in the proof of [20, Theorem 3.4], we introduce an invariant of the Cuntz semigroup called the radius of divisibility. This name is inspired by the fact (shown in Proposition 7.1) that it shares roughly the same relationship to the matricial-to-topological dimension of a recursive subhomogeneous algebra as does the radius of comparison, as defined in [21, Definition 4.1]. In fact, much as the radius of comparison has been used to show that simple approximately subhomogeneous algebras with slow dimension growth have strict comparison in their Cuntz semigroups, the radius of divisibility will be used in Corollary 7.2 to show that the Cuntz semigroups of such algebras are also almost divisible.

Although we can phrase the following definition for general e, it is probably only useful in the case where *e* is full and in the Pedersen ideal of *A*.

Definition 5.1 Let A be a C*-algebra and let $e \in A_+$. The radius of divisibility of A with respect to e is the infimum of real numbers r > 0 such that, for any continuous linear function $f: T(A) \to (0, \infty)$, there exists $a \in (A \otimes \mathcal{K})_+$ such that for all $\tau \in T(A)$,

$$|d_{\tau}(a) - f(\tau)| \leq rd_{\tau}(e).$$

We denote this quantity by rod(A, e).

For a Choquet simplex C, let us denote by Aff(C) the set of continuous affine maps C to \mathbb{R} , and by Aff(C)₊₊ the subset of Aff(C) whose range is contained in $(0, \infty)$.

Lemma 5.2 Let

$$C_1 \stackrel{\phi_2^1}{\longleftarrow} C_2 \stackrel{\phi_3^2}{\longleftarrow} \cdots$$

be an inverse sequence of Choquet simplices whose inverse limit is C. Then

- $\begin{array}{ll} \text{(i)} & \bigcup_{i=1}^{\infty} \operatorname{Aff}(C_i) \circ \phi_{\infty}^i \text{ is uniformly dense in Aff}(C); \\ \text{(ii)} & \bigcup_{i=1}^{\infty} \operatorname{Aff}(C_i)_{++} \circ \phi_{\infty}^i \text{ is uniformly dense in Aff}(C)_{++}. \end{array}$

Proof (i) is well known.

(ii) This is essentially contained in the proof of [20, Theorem 3.4]; however, for clarity, we will provide an explicit proof here. By (i), it suffices to show that if $f \in$ $\mathrm{Aff}(C_i) \circ \phi_{\infty}^i \cap \mathrm{Aff}(C)_{++}$, then $f \in \mathrm{Aff}(C_j)_{++} \circ \phi_{\infty}^j$ for some j. Let $g \in \mathrm{Aff}(C_i)$ be such that $f = g \circ \phi_{\infty}^i$; we will in fact show that $g \circ \phi_i^i \in \text{Aff}(C_i)_{++}$ for some $j \geq i$. For a contradiction, suppose that this is false; that is, that for each i > i, there exists $x_i \in C_i$ such that $g(\phi_i^i(x_i)) \le 0$. Then for $i \ge i$, set

$$\gamma_j = (\gamma_j^{(k)})_{k \ge i} := (\phi_j^i(x_j), \phi_j^{i+1}(x_j), \dots, \phi_j^{i-1}(x_j), x_j, x_{j+1}, x_{j+2}, \dots) \in \prod_{k=i}^{\infty} C_k.$$

By compactness of $\prod_{k=i}^{\infty} C_k$, let $\gamma = (\gamma^{(k)}) \in \prod_{k=i}^{\infty} C_k$ be a cluster point of the sequence (γ_j) . Since $\gamma_j^{(k+1)} \circ \phi_{k+1}^k = \gamma_j^{(k)}$ for all $k \leq j$, it follows that $\gamma^{(k+1)} \circ \phi_{k+1}^k = \gamma^{(k)}$ for all k; that is, $(\gamma^{(k)})$ defines a point γ in C. However,

$$f(\gamma) = g(\phi_{\infty}^{i}(\gamma)) \le \limsup g(\phi_{j}^{i}(x_{j})) \le 0,$$

which is a contradiction.

Proposition 5.3 Let

$$A_1 \xrightarrow{\phi_1^2} A_2 \xrightarrow{\phi_2^3} \cdots$$

be an inductive sequence of C*-algebras whose limit is A such that the maps ϕ_i^j are injective and full. Suppose e_1 is a full element in the Pedersen ideal of A_1 , and set $e = \phi_1^{\infty}(e_1)$. Then

$$rod(A, e) \leq \lim \inf rod(A_i, \phi_1^i(e_i)).$$

Proof Set $e_i := \phi_1^i(e_1)$ for all i. Let $r := \liminf \operatorname{rod}(A_i, e_i)$, and suppose that r' > r. Let $\eta = (r' - r)/2$. Let $f \in \operatorname{Aff}(T_{e \mapsto 1}(A))_{++}$. We note that $T_{e \mapsto 1}(A) = \varprojlim T_{e_i \mapsto 1}(A)$ (this is well-known in the unital case, and no tricks are needed to adapt the proof to the nonunital situation). It therefore follows from Lemma 5.2(ii) that for all i sufficiently large, there exists $g \in \operatorname{Aff}(T_{e_i \mapsto 1}(A_i))$ such that $\|g \circ \phi_\infty^i - f\| < \eta$. In particular, we may find such $g \in \operatorname{Aff}(T_{e_i \mapsto 1}(A_i))$ for some i for which $\operatorname{rod}(A_i, e_i) < r + \eta$. This means that we can find $\widehat{a} \in (A_i \otimes \mathcal{K})_+$ such that

$$|d_{\tau}(\widehat{a}) - g(\tau)| \le r + \eta$$

for all $\tau \in T_{e_i \mapsto 1}(A_i)$. Thus, with $a := \phi_i^{\infty}(\widehat{a}) \in A$, we have

$$|d_{\tau}(a) - f(\tau)| \leq |d_{\tau \circ \phi_{\infty}^{i}}(\widehat{a}) - g(\tau)| + |g \circ \phi_{i}^{\infty}(\tau) - f(\tau)| \leq r + \eta + \eta = r'.$$

Since r' > r was arbitrary, this shows that $rod(A) \le r$ as required.

6 A Computation of the Cuntz Semigroup

In Theorem 6.2, we shall show that when A is simple and exact, Cu(A) is almost unperforated, and the range of ι is uniformly dense, then Cu(A) can in fact be explicitly described purely in terms of the cone of traces T(A) paired with the Murray–von Neumann semigroup V(A). Succinctly, we show that Cu(A) has the form described in [9, Corollary 6.8]. This sort of computation is not particularly new; such Cuntz semigroup computations were pioneered by Brown, Perera, and the second author in [4], although with more hypotheses on A including unitality.

The following preliminary is in order (again, slight weakenings of this can already be found in the literature).

Lemma 6.1 Let A be a simple C^* -algebra. Then Cu(A) is almost unperforated if and only if, for $[a], [b] \in Cu(A)$, if f([a]) < f([b]) for every lower semicontinuous dimension function f for which $f([b]) < \infty$, then $[a] \le [b]$.

Proof By [18, Proposition 3.2], the "if" direction is automatic. Let us assume that $\mathcal{C}u(A)$ is almost unperforated. If $[c], [d] \in \mathcal{C}u(A)$ are such that f([c]) < f([d]) holds for every lower semicontinuous dimension function, then we must show that $[c] \leq [d]$. If we knew that f([c]) < f([d]) for the non-lower semicontinuous dimension functions, then [18, Proposition 3.2] would show that $[c] \leq [d]$; the rest of the proof overcomes this obstacle.

Given any dimension function $f \colon \mathcal{C}u(A) \to [0, \infty]$, we may define $\bar{f} \colon \mathcal{C}u(A) \to [0, \infty]$ by

$$\bar{f}([x]) = \sup_{[x'] \ll [x]} f([x']).$$

Then by [9, Lemma 4.7], \bar{f} is a lower semicontinuous dimension function on Cu(A). For $[a] \ll [c]$, we have

$$f([a]) \le \bar{f}([c]) < \bar{f}([d]) \le f([d]).$$

(The first and last inequalities are evident from the definition of \overline{f} , while the middle one is by hypothesis.) Therefore, by [18, Proposition 3.2], $[a] \leq [d]$. But since [c] is the supremum of [a] satisfying $[a] \ll [c]$, we must have $[c] \leq [d]$, as required.

In the following, we view V(A) II $Lsc(T(A), (0, \infty])$ as an ordered abelian semi-group as follows; V(A) and $Lsc(T(A), (0, \infty])$ are already ordered semigroups (with pointwise \leq giving the ordering on the latter), and we insist that their embeddings maintain the order and semigroup structures. For

$$[p] \in V(A)$$
 and $f \in Lsc(T(A), (0, \infty]),$

we set $[p] + f := g \in Lsc(T(A), (0, \infty])$ given by $g(\tau) = \tau(p) + f(\tau)$; $[p] \le f$ if and only if $\tau(p) < f(\tau)$ for all $\tau \in T(A)$, while $f \le [p]$ if and only if $f(\tau) \le \tau(p)$ for all $\tau \in T(A)$.

Theorem 6.2 Let A be a simple, exact C^* -algebra such that Cu(A) is almost unperforated and the range of ι is uniformly dense. Then Cu(A) is isomorphic, as an ordered semigroup, to $V(A) \coprod Lsc(T(A), (0, \infty])$. The isomorphism sends $[a] \in Cu(A)$ to $[p] \in V(A)$ if [a] = [p] for some projection $p \in (A \otimes \mathcal{K})_+$, and to the function $\iota(a)$ otherwise.

Proof The statement of the proposition implicitly defines a map

$$\Phi \colon \mathcal{C}u(A) \to V(A) \coprod \mathsf{Lsc}(T(A), (0, \infty]).$$

Let us first verify that Φ is an order embedding, *i.e.*, that $[a] \leq [b]$ if and only if $\Phi([a]) \leq \Phi([b])$. This will require only that $\mathcal{C}u(A)$ is almost unperforated. Four different cases need to be checked, depending on whether or not each of [a], [b] is in V(A).

It is trivial if both are in V(A). By using Proposition 6.1, we obtain the "if" direction when $[a] \in V(A)$. However, if $[a] \in V(A)$ and [a] < [b], then by [16, Proposition 2.2], there exists a nonzero [x] such that $[a] + [x] \le [b]$. Since A is simple, $d_{\tau}(x) > 0$ and so $\widehat{[a]}(\tau) < \widehat{[b]}(\tau)$ for all τ .

The "only if" direction is automatic if $[a] \notin V(A)$. On the other hand, if $[a] \notin V(A)$ and $\widehat{[a]} \leq \widehat{[b]}$ pointwise then, again using [16, Proposition 2.2] and simplicity of A, we have

$$\widehat{[a']}(\tau) < \widehat{[a]}(\tau) \leq \widehat{[b]}(\tau)$$

for all τ , and therefore by Proposition 6.1, $[a'] \leq [b]$. Since [a] is the supremum of $[a'] \ll [a]$, we have $[a] \leq [b]$. This concludes the verification that Φ is an order embedding.

Now we will show that Φ is surjective. Obviously, V(A) is in the range of Φ . We shall therefore show that $Lsc(T(A), (0, \infty])$ is contained in the range of Φ . By Proposition 4.1, it suffices to show that the range of ι contains $Aff(T_{\ell \mapsto 1}(A), (0, \infty))$.

Namely, given $f \in \text{Aff}(T_{e \mapsto 1}(A), (0, \infty))$, let $\epsilon_1 > \epsilon_2 > \cdots$, converging to 0, such that $f(\tau) > \epsilon_1$ for all n. Since the range of ι is dense, we may find $[b_n] \in \mathcal{C}u(A)$ such that

$$\iota(b_n)(\tau) \in (f(\tau) - \epsilon_n, f(\tau) - \epsilon_{n+1})$$

for all $\tau \in T_{e \mapsto 1}(A)$. By Proposition 6.1, $([b_n])$ is an increasing sequence, and its supremum [b] clearly satisfies $\iota(b) = f$, as required.

7 Simple Approximately Subhomogeneous Algebras With Slow Dimension Growth

The following result is in all likelihood true without the assumption of a compact primitive ideal space, but we do not require this generality for the applications we have in mind.

Proposition 7.1 Let A be subhomogeneous with Prim(A) compact, and let e be a full, positive element in the Pedersen ideal of A. It follows that

(7.1)
$$\operatorname{rod}(A, e) \le 16R_{(d+4):r}(e) := 16 \sup_{\pi \text{ irred. rep.}} \frac{d_{\operatorname{top}}(\pi) + 4}{\operatorname{Rank} \pi(e)}.$$

Proof This proof is contained in the proof of [20, Theorem 3.4]. We shall explain exactly how, since the statement of [20, Theorem 3.4] neither makes reference to the radius of divisibility, nor handles the nonunital case. Set r to be the right-hand side of (7.1) for convenience, and let a continuous linear function $f: T(A) \to (0, \infty)$ be given. By Proposition 3.4 we have that $T_{e\mapsto 1}(A)$ is a compact base for the space of densely defined lower semicontinuous traces. We therefore need only prove that there exists $a \in (A \otimes \mathcal{K})_+$ such that $|d_{\tau}(a) - f(\tau)| \le r$ for all $\tau \in T_{e\mapsto 1}(A)$, and, of course, it in fact suffices to show this only for extreme points of $T_{e\mapsto 1}(A)$.

As long as r is finite, it follows from [19, Corollary 3.3] that A is a recursive subhomogeneous algebra, so let us consider it to be equipped with a recursive subhomogeneous decomposition. For $1 \le i \le n$, let $M_{n_i}(X_i)$ be the i-th matrix block of A, $X_i^{(0)}$ the i-th clutching space, A_i the i-th stage algebra, and $\phi_i \colon A_i \to M_{n_i}$ the i-th clutching homomorphism. The irreducible representations of A correspond to evaluating an element of A at a point

$$x \in X^{(1)} := \bigcup_{i=1}^{l} X_i \backslash X_i^{(0)}.$$

Let us denote such a representation by π_x , and let Tr denote the canonical normalized trace on M_n (for any n). The extreme points of $T_{e\mapsto 1}(A)$ are all multiples of $\tau_x:=\operatorname{Tr}\circ\pi_x$; therefore, we must verify that $|d_{\tau_x}(a)-f(\tau)|\leq rd_{\tau_x}(e)$ for all $x\in X^{(1)}$. We note here that $d_{\tau_x}(b)=\operatorname{rank}(\pi_x(b))/n_i=\operatorname{rank}(b(x))/n_i$ for any $b\in A_+$ and $x\in X_i$. We can therefore finally characterize our requirement in terms of ranks of positive

operators:

$$\left|\frac{\operatorname{rank}(a(x))}{n_i} - f(\tau_x)\right| \le r \frac{\operatorname{rank}(e(x))}{n_i} = 16 \frac{\dim(X_i) + 4}{n_i}.$$

The existence of such an *a* now follows verbatim from the proof of [20, Theorem 3.4, p. 239].

Corollary 7.2 If A is a simple, nonelementary, approximately subhomogeneous algebra with slow dimension growth, then ι is surjective, and $\mathfrak{C}u(A)$ is as described in Theorem 6.2

Proof The range of ι is dense by Propositions 5.3 and 7.1, together with noting that simplicity and nonelementarity implies that min Rank $\pi(\phi_1^{\infty}(a)) \to \infty$ for every nonzero π . We have almost unperforation by [19, Corollary 5.9]. The conclusion follows from Theorem 6.2.

Corollary 7.3 Let A be a simple, separable, non-type I approximately subhomogeneous algebra. Then the following are equivalent.

- (i) A is Z-stable.
- (ii) A has slow dimension growth.
- (iii) A has finite decomposition rank.

Proof (i) \Leftrightarrow (ii) is [22, Corollary 9.2], which relies on Corollary 7.2.

 $(iii) \Rightarrow (i)$ is [22, Theorem 8.5].

Finally, (i) \Rightarrow (iii) is the main result of [8].

Acknowlegments The authors would like to thank George Elliott and Victor Kaftal for helpful comments.
