(Received 25 January 2025; revised 12 April 2025; accepted 03 July 2025)

Abstract: The crystal structure of cabotegravir has been solved and refined using synchrotron X-ray powder diffraction data and optimized using density functional theory techniques. Cabotegravir crystallizes in space group $P2_12_12$ (#18) with $a = 31.4706(11)$, $b = 13.4934(3)$, $c = 8.43811(12)$ Å, $V = 3,583.201(18)$ Å³, and $Z = 8$ at 298 K. The crystal structure consists of stacks of roughly parallel molecules along the c -axis. The molecules form layers parallel to the bc -plane. O–H...O hydrogen bonds link one of the two independent molecules into chains along the b -axis. The powder pattern has been submitted to the International Centre for Diffraction Data (ICDD®) for inclusion in the Powder Diffraction File™ (PDF®).

Key words: cabotegravir, Vocabria, crystal structure, Rietveld refinement, density functional theory

I. INTRODUCTION

Cabotegravir (sold under the brand name Vocabria, among others) is used for the treatment of HIV/AIDS. Cabotegravir is an HIV-1 integrase strand inhibitor and can be administered alone or in combination with rilpivirine. The systematic name (CAS Registry No. 1051375-10-0) is (3R,6S)-N-[(2,4-difluorophenyl)methyl]-10-hydroxy-6-methyl-8,11-dioxo-4-oxa-1,7-diazatricyclo[7.4.0.0^{3,7}]trideca-9,12-diene-12-carboxamide. A two-dimensional molecular diagram of cabotegravir is shown in Figure 1.

Preparation of cabotegravir is claimed in International Patent Application WO 2011/119566 A1 (Wang et al., 2011; GlaxoSmithKline). A new crystalline Form B of the sodium salt of cabotegravir is claimed in European Patent 3363802 B1 (Adamer and Thaler, 2017; Sandoz), and powder data for Form B and the prior art Form A are provided. Powder data for crystalline cabotegravir prepared according to Example D of WO 2011/119566 are also provided. A powder pattern for crystalline cabotegravir is also reported by Zhou et al. (2018). An orthorhombic unit cell, determined by 3D electron diffraction, with $a = 7.26$, $b = 7.29$, and $c = 32.3$ Å, was reported by Johnstone et al. (2019). A synchrotron powder pattern from this study of a commercial sample of cabotegravir bears only a slight resemblance to those of Wang et al. (2011) and Zhou et al. (2018) (Figure 2), and we are hard-pressed to conclude that it is the same as the prior art. The cell reported by Johnstone et al. (2019) does not index this pattern.

This work was carried out as part of a project (Kaduk et al., 2014) to determine the crystal structures of large-

volume commercial pharmaceuticals and include high-quality powder diffraction data for them in the Powder Diffraction File™ (Kabekkodu et al., 2024).

II. EXPERIMENTAL

Cabotegravir was a commercial reagent, purchased from TargetMol (Batch #T6098), and was used as received. The white powder was packed into a 0.5-mm-diameter Kapton capillary and rotated during the measurement at ~2 Hz. The powder pattern was measured at 298(1) K at the Wiggler Low Energy Beamline (Leontowich et al., 2021) of the Brockhouse X-Ray Diffraction and Scattering Sector of the Canadian Light Source using a wavelength of 0.819563(2) Å (15.1 keV) from 1.6 to 75.0° 2θ with a step size of 0.0025° and a collection time of 3 minutes. The high-resolution powder diffraction data were collected using eight Dectris Mythen2 X series 1K linear strip detectors. NIST SRM 660b LaB₆ was used to calibrate the instrument and refine the monochromatic wavelength used in the experiment.

In contrast to most pharmaceuticals we have studied at this beamline, cabotegravir sample exhibits a prominent background peak at 6.3° 2θ, indicating that the sample is not completely crystalline. Both N-TREOR (Altomare et al., 2013) and DICVOL06 (Louër and Boulton, 2007), as incorporated into FOX (Favre-Nicolin and Černý, 2002), suggested a primitive orthorhombic unit cell with $a = 8.4414$, $b = 13.4993$, $c = 31.4811$ Å, $V = 3,587.4$ Å³, and $Z = 8$. Other programs suggested larger unit cells. EXPO2014 (Altomare et al., 2013) suggested space group $P2_12_12$. A reduced cell search of the Cambridge Structural Database (Groom et al., 2016), combined with the chemistry H, C, N,

Corresponding author: James Kaduk; Email: kaduk@polycrystallography.com

Figure 1. The two-dimensional structure of cabotegravir.

O, and F only, yielded 1 hit, but no structures of cabotegravir or its derivatives.

The cabotegravir molecular structure was downloaded from PubChem (Kim et al., 2023) as Conformer3D_COMPOUND_CID_54713659.sdf. It was converted to a *.mol2 file using Mercury (Macrae et al., 2020). The structure was solved by Monte Carlo-simulated annealing techniques as implemented in EXPO2014 (Altomare et al., 2013), using two molecules as fragments. A chemically plausible structure was obtained, refined, and optimized, but the agreement of the Rietveld-refined and density functional theory (DFT)-optimized structures was outside the normal range for correct structures (van de Streek and Neumann, 2014); the root-mean-square (rms) Cartesian displacement was 1.08 Å.

A Le Bail fit using this cell and space group $P222$ fit all the peaks, so we suspected that the space group was incorrect. Le Bail fits in six additional proper orthorhombic space groups ($P2_12_1$, $P2_122_1$, $P2_12_12$, $P2_122$, $P22_12$, and $P222_1$), as well as monoclinic space groups $P2_111$, $P12_11$, and $P112_1$, and the triclinic space group $P1$ were carried out. Space group $P2_12_1$ yielded a fit as good as $P1$, so it was adopted for structure solution, after converting the cell to the standard setting $P2_12_12$. The structure was resolved in this new space group using EXPO2014.

Rietveld refinement was carried out with GSAS-II (Toby and Von Dreele, 2013). Only the 2.5–45.0° portion of the pattern was included in the refinements ($d_{\min} = 1.071$ Å). All non-H-bond distances and angles were subjected to restraints, based on a Mercury/Mogul Geometry Check (Bruno et al., 2004; Sykes et al., 2011). The Mogul average and standard deviation for each quantity were used as the restraint parameters. The two aromatic ring systems and the amide group in each molecule were restrained to be planar. The restraints contributed 16.1% to the overall χ^2 . The hydrogen atoms were included in calculated positions, which were recalculated during the refinement using Materials Studio (Dassault Systèmes, 2023). The U_{iso} of the heavy atoms were grouped by chemical similarity. The U_{iso} of the H atoms were fixed at 1.3× the U_{iso} of the heavy atoms to which they are attached. The structure apparently contains a small void on a twofold axis at 0, 1/2, 0.211. Placing an O atom (water molecule) at this position and refining yielded low occupancy and movement too close to other atoms, so it was deleted from the model. The peak profiles were described using the generalized (Stephens, 1999) microstrain model. The background was modeled using a three-term shifted Chebyshev polynomial, with peaks at 6.29 and 10.57° to model the scattering from the amorphous portion of the sample and the Kapton capillary.

The final refinement of 193 variables using 17,001 observations and 166 restraints yielded the residual $R_{\text{wp}} = 0.09730$.

Figure 2. Comparison of the synchrotron pattern of cabotegravir (black) to those reported by Adamer and Thaler (2017) (red) and Zhou et al. (2018) (green). The literature patterns (measured using Cu K_{α} radiation) were digitized using UN-SCAN-IT (Silk Scientific, 2013) and converted to the synchrotron wavelength of 0.819563(2) Å using JADE Pro (MDI, 2024). Image generated using JADE Pro (MDI, 2024).

Figure 3. The Rietveld plot for cabotegravir. The blue crosses represent the observed data points, and the green line represents the calculated pattern. The cyan curve indicates the normalized error plot, and the red line indicates the background curve. The blue tick marks indicate the cabotegravir peak positions. The vertical scale has been multiplied by a factor of $10\times$ for $2\theta > 17.5$.

The largest peak (1.81 \AA from C71) and hole (1.17 \AA from F47) in the difference Fourier map were $0.97(21)$ and $-0.77(21) \text{ e\AA}^{-3}$, respectively. The final Rietveld plot is shown in Figure 3. The largest features in the normalized error plot are in the shapes and intensities of some of the strong low-angle peaks.

The crystal structure of cabotegravir was optimized (fixed experimental unit cell) with density functional theory techniques using VASP (Kresse and Furthmüller, 1996) through the MedeA graphical interface (Materials Design, 2024). The calculation was carried out on 32 cores of a 144-core (768-GB memory) HPE Superdome Flex 280 Linux server at North Central College. The calculation used the GGA-PBE functional, a plane wave cutoff energy of 400.0 eV , and a k -point spacing of 0.5 \AA^{-1} , leading to a $1 \times 1 \times 2$ mesh, and took ~ 182.7 hours. Single-point density functional calculations (fixed experimental cell) and population analysis were carried out using CRYSTAL23 (Erba et al., 2023). The basis sets used for the H, C, N, and O atoms in the calculation were those of Gatti et al. (1994), while the basis set for F was that of Peintinger et al. (2013). The calculations were run on a 3.5-GHz PC using eight k -points and the B3LYP functional and took ~ 7.2 hours.

III. RESULTS AND DISCUSSION

The sample of cabotegravir studied here is only partially crystalline. The crystalline component exhibits only slight similarities to the crystalline cabotegravir of the prior art, so it is uncertain how relevant our material is to that used in the pharmaceutical industry. It is apparently a new polymorph.

The rms difference of the non-H atoms in the Rietveld-refined and VASP-optimized structures, calculated using the Mercury CSD-Materials/Search/Crystal Packing Similarity tool, is 0.644 \AA . The rms Cartesian displacements of the non-H atoms in the Rietveld-refined and VASP-optimized

structures of molecules 1 and 2, calculated using the Mercury Calculate/Molecule Overlay tool, are 0.529 and 0.449 \AA (Figures 4 and 5). The largest differences are in the orientation of the difluorophenyl ring of molecule 1 and the orientation of the fused ring system of molecule 2. The agreements are

Figure 4. Comparison of the Rietveld-refined (red) and VASP-optimized (blue) structures of molecule 1 of cabotegravir. The root-mean-square Cartesian displacement is 0.529 \AA . Image generated using Mercury (Macrae et al., 2020).

Figure 5. Comparison of the Rietveld-refined (red) and VASP-optimized (blue) structures of molecule 2 of cabotegravir. The root-mean-square Cartesian displacement is 0.449 \AA . Image generated using Mercury (Macrae et al., 2020).

Figure 6. The asymmetric unit of cabotegravir, with the atom numbering. Image generated using Mercury (Macrae et al., 2020).

outside the normal range for correct structures (van de Streek and Neumann, 2014). The asymmetric unit is illustrated in Figure 6. The remaining discussion will emphasize the VASP-optimized structure.

Almost all of the bond distances and bond angles, and most of the torsion angles, fall within the normal ranges indicated by a Mercury Mogul Geometry check (Macrae et al., 2020). The C17–C12–N8 angle of 115.4° (average = $112.0(10)^\circ$; Z-score = 3.3) and the C69–C70–C71 angle of 120.8° (average = $121.2(16)^\circ$; Z-score = 4.3) are flagged as unusual. Torsion angles involving rotations about the C23–C24 and C69–C70 bonds lie in valleys of broad bimodal distributions. Torsion angles involving rotations about the C20–C22 bond are very unusual. The confirmation of the amide group in molecule 1 is unusual.

The two independent molecules have very different conformations (Figure 7); the rms Cartesian displacement of the non-H atoms is 2.255 Å. Molecule 2 is roughly planar, while molecule 1 is kinked at the amide group (Figure 8). Quantum chemical geometry optimization of isolated cabotegravir molecules (DFT/B3LYP/6-31G*/water) using Spartan'24 (Wavefunction, 2023) indicated that the observed conformation of molecule 1 is 6.4 kcal/mol lower in energy than that of molecule 2, but that the local energy minimum of molecule 2 is 8.1 kcal/mol lower in energy. Both local minima and the global minimum-energy conformation are kinked, resembling molecule 1 more than molecule 2.

Figure 7. Comparison of the VASP-optimized structures of molecule 1 (green) and molecule 2 (orange) of cabotegravir. The root-mean-square Cartesian displacement of the non-H atoms is 2.255 Å. Image generated using Mercury (Macrae et al., 2020).

Figure 8. Comparison of the two independent VASP-optimized cabotegravir molecules. Molecule 1 (kinked) is above, and molecule 2 is below.

The crystal structure (Figure 9) consists of stacks of roughly parallel molecules along the *c*-axis. The kinked phenyl ring of molecule 1 fits into the plane of the adjacent molecules. The molecules form layers parallel to the *bc*-plane. The mean planes of the fused ring systems in molecules 1 and 2 are approximately (12, −4, 7) and (16, −3, −6); the average plane is approximately (4, −1, −2). The distance between adjacent ring planes is approximately 3.6 Å. Hydrogen bonds link molecule 2 into chains along the *b*-axis (Figure 10). The Mercury Aromatics Analyser indicates two moderate interactions between the phenyl rings of molecules 1 and 2, with the distances of 5.67 and 6.74 Å.

Analysis of the contributions to the total crystal energy of the structure using the Forcite module of Materials Studio (Dassault Systèmes, 2023) indicates that angle and torsion distortion terms dominate the intramolecular energy, but that bond distortion terms are also important. The intermolecular energy is dominated by van der Waals repulsions and electrostatic attractions, which in this force field-based analysis also include hydrogen bonds. The hydrogen bonds are better discussed using the results of the DFT calculation.

Molecule 2 participates in more intra- and inter-molecular hydrogen bonds than molecule 1 (Table I). There are four classical hydrogen bonds. In molecule 1, the hydroxyl group O5–H40 forms a strong intramolecular O–H...O hydrogen bond to the adjacent carbonyl group O6. In molecule 2, the equivalent hydroxyl group O51–H86 forms a strong O–H...O hydrogen bond to another molecule 2, resulting in chains along the *b*-axis

Figure 9. The crystal structure of cabotegravir, viewed down the b -axis. Image generated using Diamond (Crystal Impact, 2023).

Figure 10. The hydrogen-bonded chains of molecule 2 in the crystal structure of cabotegravir. The b -axis is horizontal.

(Figure 10). The chains have the graph set $C1, I(7)$ (Etter, 1990; Bernstein et al., 1995; Motherwell et al., 2000). The energies of the O–H \cdots O hydrogen bonds were calculated using the correlation of Rammohan and Kaduk (2018). In molecule 1, the amino group N10–H41 forms a weak intermolecular N–H \cdots C hydrogen bond to C72, while in molecule 2, the equivalent N56–H87 forms a strong intramolecular N–H \cdots O hydrogen bond to the carbonyl O52. The energy of the N–H \cdots O hydrogen bond was

calculated using the correlation of Wheatley and Kaduk (2019). Several C–H \cdots O and C–H \cdots N hydrogen bonds contribute to the lattice energy, and the pattern of hydrogen bonding is different for molecules 1 and 2.

The volume enclosed by the Hirshfeld surface of cabotegravir (Figure 11; Hirshfeld, 1977; Spackman et al., 2021) is 885.79 Å³, 98.86% of one-fourth of the unit cell volume. The packing density is thus typical. The only significant close

Figure 11. The Hirshfeld surface of cabotegravir. Intermolecular contacts longer than the sum of the van der Waals radii are colored blue, and contacts shorter than the sum of the radii are colored red. Contacts equal to the sum of the radii are white. Image generated using CrystalExplorer (Spackman et al., 2021).

contacts (red in Figure 11) involve the hydrogen bonds. The volume/non-hydrogen atom is smaller than usual at 15.4 Å³.

The Bravais–Friedel–Donnay–Harker (Bravais, 1866; Friedel, 1907; Donnay and Harker, 1937) algorithm suggests that we might expect platy morphology for cabotegravir, with {100} as the major faces, as expected from both the anisotropy of the lattice parameters and the layered structure. A fourth-order spherical harmonic model was included in the refinement. The texture index was 1.076(4), indicating that the preferred orientation was small in this rotated capillary specimen.

DEPOSITED DATA

The powder pattern of cabotegravir from this synchrotron dataset has been submitted to the International Centre for Diffraction Data (ICDD) for inclusion in the Powder Diffraction File™. The Crystallographic Information Framework (CIF) files containing the results of the Rietveld refinement (including the raw data) and the DFT geometry optimization were deposited with the ICDD. The data can be requested at pdj@icdd.com.

ACKNOWLEDGEMENTS

We thank Adam Leontowich for his assistance in the data collection. We also thank the ICDD team – Megan Rost, Steve

Trimble, and Dave Bohnenberger – for their contribution to research, sample preparation, and in-house XRD data collection and verification.

FUNDING STATEMENT

Part or all of the research described in this paper was performed at the Canadian Light Source, a national research facility of the University of Saskatchewan, which is supported by the Canada Foundation for Innovation (CFI), the Natural Sciences and Engineering Research Council (NSERC), the Canadian Institute of Health Research (CIHR), the Government of Saskatchewan, and the University of Saskatchewan. This work was partially supported by the International Centre for Diffraction Data.
