INTRODUCTION

The radiocarbon ages of dendrochronologically dated wood samples, each covering 10 years, are reported back to 2500 yr BC. The decadal calibration curve constructed from these data is an extension of the curve previously given for the AD interval (Stuiver, 1982). A major difference with the previous work, however, is the assessment of the error in the radiocarbon age determination. Whereas previously this error was only based on the Poisson counting statistics of the accumulated number of counts for the sample and standards, the current calibration error is based on an estimate of the reproducibility in the radiocarbon activity determination. As a consequence, the uncertainty in the current calibration curve is, on average, 1.6 times that of the AD curve previously given.

The radiocarbon ages obtained for the decadal wood samples (Fig 1 and Table 1) were used for the construction of the bi-decadal calibration curves also reported in this issue (Stuiver & Pearson, 1986; Pearson & Stuiver, 1986). Because the average ^{14}C age of a bi-decadal wood sample is determined from one 20-yr determination by the Belfast laboratory, and from two 10-yr determinations of the Seattle laboratory, the resulting bi-decadal calibration curve is more precisely defined than the decadal curve published here. For most purposes, therefore, the internationally recommended bi-decadal curves should be used. However, the decadal curve is important when investigators are interested in the fine structure of ^{14}C age calibration of samples formed during a short interval (*ie*, <2 decades).

DENDROCHRONOLOGY AND SAMPLE TREATMENT

The trees used for the AD interval were either Douglas Fir (*Pseudotsuga menziesii*) from the US Pacific Northwest, or Sequoia (*Sequoiadendron giganteum*) from California. The dendrochronologic work on these materials is summarized in Table 2, and in Stuiver (1982) and Stuiver and Pearson (1986). Nearly all the BC material was dendro-dated by one of the authors (Becker, 1983). A limited number of samples from the Irish Oak chronology (Pilcher *et al.*, 1984) was used near 500 BC.

Table 2 also lists the type of wood pretreatment. The de Vries method (Stuiver & Quay, 1980) was used for most of the AD wood samples, whereas alpha cellulose (Stuiver, Burk & Quay, 1984) was prepared for samples covering the BC interval. The de Vries method does not remove all components added after the year of growth, but our measurements show the influence

of incomplete removal of late additions to be limited to 2 or 3 ^{14}C years (Stuiver & Quay, 1981).

TECHNIQUE AND LABORATORY REPRODUCIBILITY

The ^{14}C community has traditionally been satisfied with reporting age errors based on counting statistics alone. This clearly was an unwise choice as interlaboratory comparisons of results obtained for the same samples show substantial under-reporting of the ^{14}C age errors (International Study Group, 1982; Stuiver, 1982).

Repeat analyses of samples with ^{14}C ages <4000 yr yield an error for the Seattle laboratory equal to 1.6 times the Poisson counting error (Stuiver, 1982; Stuiver & Pearson, 1986). This 1.6 "error multiplier" is only valid for the age ranges given in this paper, and should not be applied to all samples measured in the Seattle laboratory (Stuiver, Pearson & Braziunas, 1986). The error reported with the ^{14}C ages in Table 1 is the actual reproducibility standard deviation. Suitable proof that this standard deviation indeed accounts for the entire uncertainty in the measuring process was derived from a comparison with the ^{14}C ages obtained by the Belfast laboratory (Pearson *et al.*, 1986) on contemporaneous wood. The differences in ^{14}C ages of 214 sample pairs (Stuiver & Pearson, 1986, Fig 3) are fully compatible with the quoted errors of the Seattle and Belfast laboratories. Similar agreement is obtained when subdividing the paired samples of the AD 1950-2500 BC period in AD and BC intervals (Figs 2 and 3), and by comparing Belfast Irish Oak results with Seattle German Oak results (Fig 4). Four CO_2 gas proportional counters (Stuiver, Robinson & Yang, 1979) were used for the ^{14}C activity determinations. The counter volumes are ca 4L; when operated at a filling pressure of 3.0 to 3.5 atmospheres the count rates for 'old' NBS oxalic acid are 90 to 100 counts per minute. Background count rates are 1.5 to 2.5 counts per minute, depending on the counter.

SYSTEMATIC DIFFERENCES BETWEEN LABORATORIES

Systematic ^{14}C age differences are discussed in Stuiver (1982); Stuiver and Pearson (1986) and Stuiver *et al.* (1986). It was shown that systematic offsets of the Seattle data are limited to a few years for the age ranges discussed here, and that ^{14}C ages of wood of the same age from Ireland, south Germany, and the northwest United States differed, on average, by a few years only. Thus, although our curves are based on wood from trees of dif-

ferent regions, identical results would have been obtained if all measurements had been made on one tree from one locality.

CALIBRATION INSTRUCTIONS

The calibration instructions are similar to those given in Stuiver and Pearson (1986) and Pearson and Stuiver (1986) and are repeated here. The Figure 1 calibration curves consist of three lines. The center line is the actual calibration curve whereas the outer lines indicate the one sigma (standard deviation) uncertainty in the calibration curve. The calibration curve depicts the (non-linear) transformation of ^{14}C ages to calibrated AD/BC (or BP) ages. The nomenclature adopted for the dendro (calendar) year time scale is cal AD/BC or cal BP. The cal AD/BC ages are plotted along the lower horizontal axis and the cal BP ages along the upper one.

Cal BP ages are relative to the year AD 1950, with 0 cal BP equal to AD 1950. The relationship between cal AD/BC and cal BP ages is simple: cal BP = 1950 - cal AD, and cal BP = 1949 + cal BC. The switch from 1950 to 1949 when converting BC ages is caused by the absence of the zero year in the AD/BC chronology (when progressing from 1 BC to AD 1, the cal BP ages should be without a gap).

The conversion of a ^{14}C age to cal age is straightforward: 1) draw a horizontal (parallel to the bottom axis) line (A) through the ^{14}C age to be converted, and 2) draw vertical lines through the intercept(s) of line A and the calibration curve (center line). The cal AD/BC ages can be read at the bottom axis, the cal BP ages at the top. A single ^{14}C age can correspond with multiple cal ages, due to past changes in atmospheric ^{14}C levels (see Stuiver, 1982 for illustration).

The user has to determine the calibrated ages from the Figure 1 graphs by drawing lines. An alternate approach is the use of Table 3, where the cal ages are listed for ^{14}C ages that increase by 20-year steps. Obviously the user has to interpolate between the 20-yr steps of ^{14}C ages and sigmas if further fine tuning is desired.

The conversion of the standard error in the ^{14}C age into a range of cal AD/BC (BP) ages is more complicated. The user should first determine whether he/she wants to use 1) the laboratory quoted error (see Stuiver & Pearson, 1986 for a discussion) or 2) increase the quoted error by a known "error multiplier." Once the sample σ has been targeted, the curve σ (one standard deviation) should be read from the calibration curve by taking the difference in ^{14}C years between center curve and outer curve(s) in Figure 1. The curve σ should then be used to calculate total

$$\sigma = \sqrt{(\text{sample } \sigma)^2 + (\text{curve } \sigma)^2}$$

(Stuiver, 1982).

Horizontal lines should now be drawn through the ^{14}C age + total σ , and ^{14}C age - total σ value. The vertical lines, drawn through the intercepts with the CENTRAL curve, yield the outer limits of possible cal AD/BC (or BP) ages that are compatible with the sample standard deviation.

The above procedure was used to derive the "ranges" of cal AD/BC (BP) ages listed in Table 3.

The conversion procedure yields 1) single or multiple cal AD/BC (BP) ages that are compatible with a certain ^{14}C age, and 2) the range(s) of cal ages that corresponds to the standard deviation in the ^{14}C age. The probability that a certain cal age is the actual sample age may be quite variable within the cal age range. Higher probabilities are encountered around the intercept ages. Low, or near zero probabilities are encountered when part of the calibration curve 'snakes' outside the total σ boundaries. The non-linear transform of a Gaussian standard deviation around a ^{14}C age into cal AD/BC (BP) ages leads to a very complex probability distribution that can only be calculated with the aid of computers. We are currently developing suitable programs for these probability calculations, and plan to make these programs available in the near future.

The calibration data presented in this paper are to be used for samples formed in isotopic (^{14}C) equilibrium with atmospheric CO_2 . Although the wood samples were collected from specific regions (Ireland, Germany and western USA) the calibration data can be used for a large part of the Northern Hemisphere (Stuiver, 1982). However, systematic age differences are possible for Southern Hemispheric samples where ^{14}C ages of wood samples tend to be approximately 30 years older (Lerman, Mook & Vogel, 1970; Vogel, Fuls & Visser, 1986). Thus, ^{14}C ages of Southern Hemispheric samples should be reduced by 30 years before being converted into a cal AD/BC (BP) age.

MARINE SAMPLE AGES

The calibration curves should be applied only for age conversion of samples that were formed in equilibrium with atmospheric CO_2 . Conventional ^{14}C ages of materials not in equilibrium with atmospheric reservoirs do not take into account the off-set in ^{14}C age that may occur (Stuiver & Polach, 1977). This off-set, or reservoir deficiency, has to be deducted from the reported ^{14}C age before any attempt can be made to convert to cal AD/BC (BP) ages. The reservoir deficiency is time-dependent for the mixed layer of the ocean. Model calculated calibration curves for marine samples are listed separately in this volume (Stuiver, Pearson & Braziunas, 1986). This paper also contains a plot of the Table 1 $\Delta^{14}\text{C}$ values.

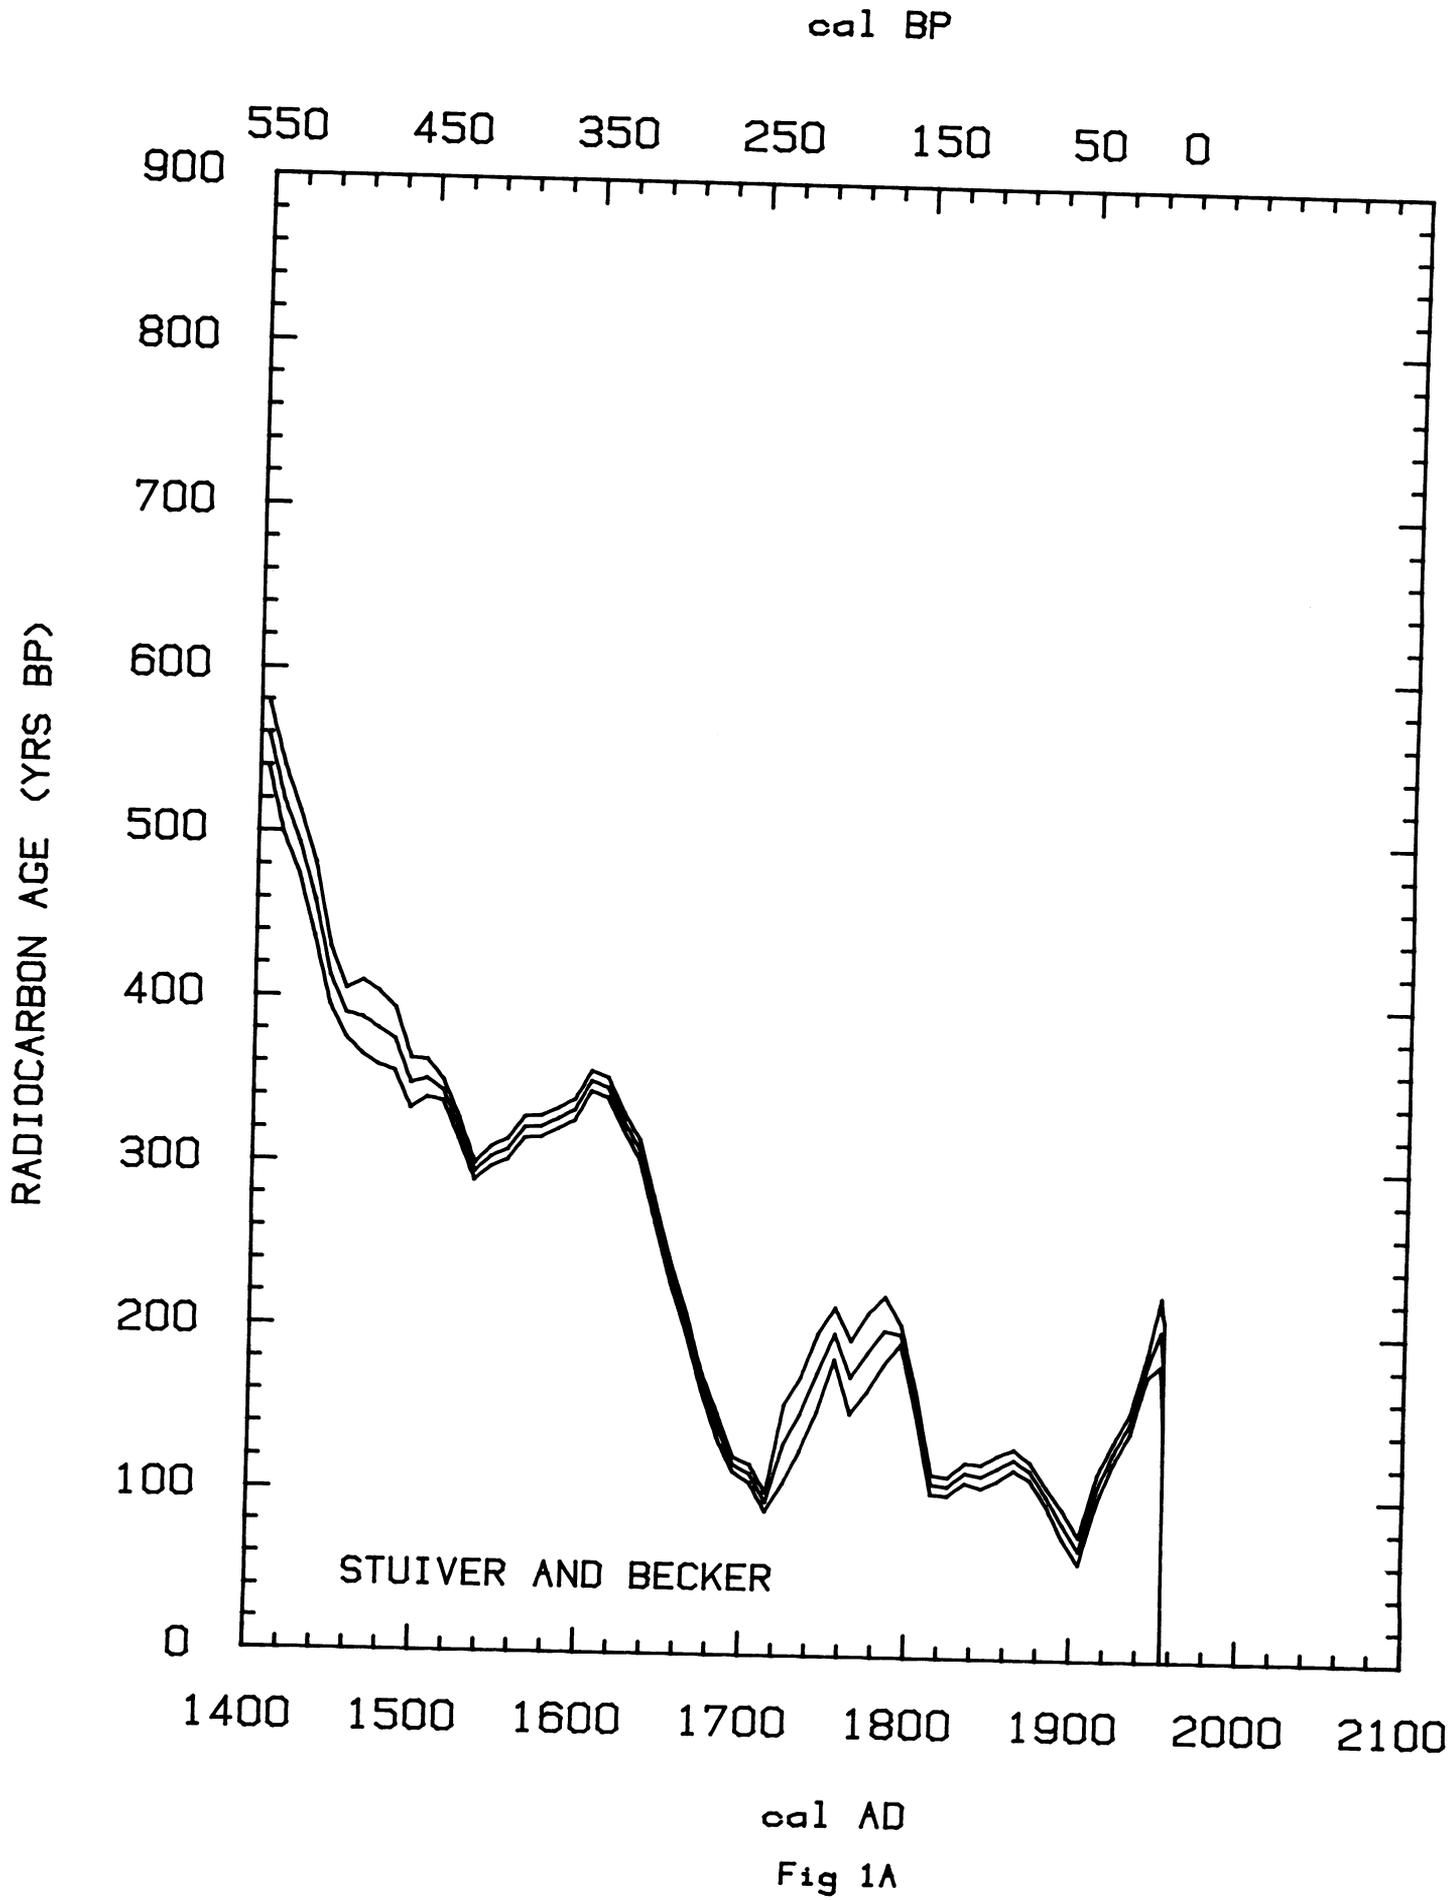

ACKNOWLEDGMENTS

P J Wilkinson dedicated much time and care to the high-precision measurements. P J Reimer's computer virtuosity was of critical importance for producing the graphs, tables, and statistical analysis.

Dendrochronologic determinations were made by M Parker, Vancouver, British Columbia, Canada, D Eckstein, University of Hamburg, West Germany, and H Garfinkel, University of Washington. The radiocarbon measurements of the Seattle Laboratory were supported through the National Science Foundation grants ATM-8318665 of the Climate Dynamics Program, and EAR-8115994 of the Environmental Geosciences program.

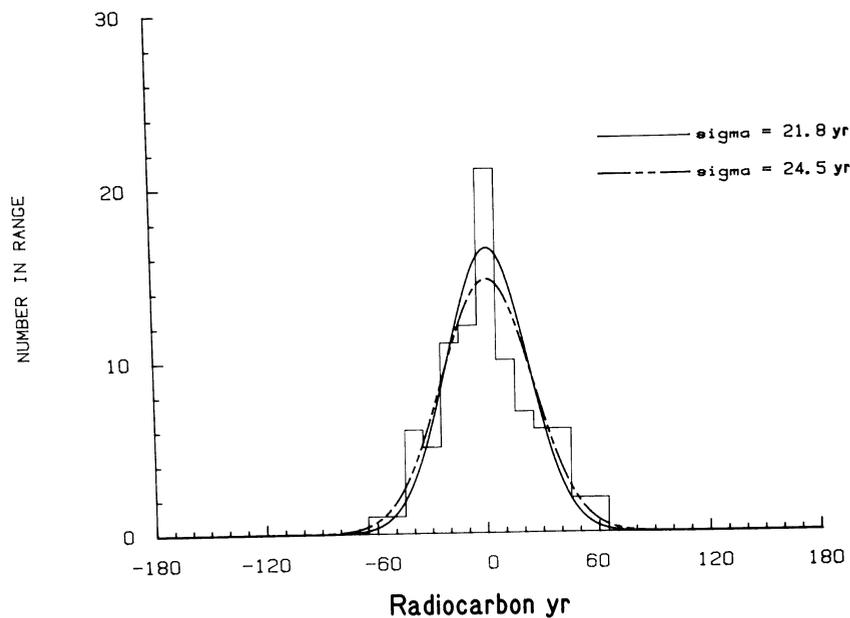

Fig 2. The distribution of ^{14}C age differences of contemporaneous sample pairs measured in Belfast and Seattle. All pairs are from the AD interval. Based on the laboratory precisions, the expected standard deviation is 21.8 yr, actual standard deviation is 24.5 yr.

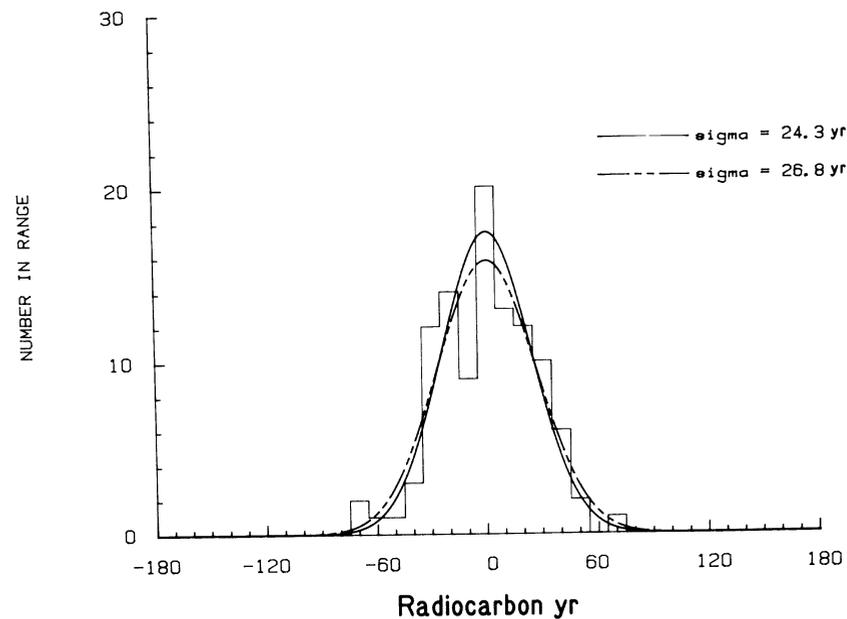

Fig 4. The distribution of ^{14}C age differences of contemporaneous sample pairs measured in Belfast (Irish Oak) and Seattle (South German Oak). Based on the laboratory precisions, the expected standard deviation in the age differences is 24.3 yr, actual standard deviation is 26.8 yr.

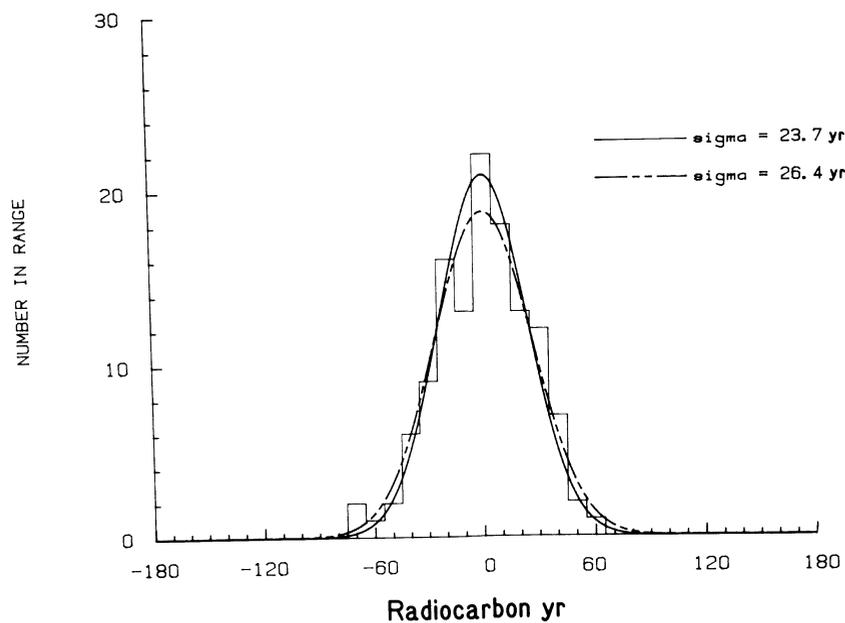

Fig 3. The distribution of ^{14}C age differences of contemporaneous sample pairs measured in Belfast and Seattle. All pairs are from the BC interval. The expected standard deviation, based on the precision quoted by the laboratories, is 23.7 yr. Actual standard deviation is 26.4 yr.

TABLE 1-A

The radiocarbon age determinations were made at the University of Washington (Seattle). The cal AD/BC ages (or cal BP) represent the mid-points of 10-year wood sections, except as noted with asterisks, when 20-year samples were needed to obtain the quantity of treated wood used for a measurement. The standard deviation of the age and Δ values includes a 1.6 lab error multiplier (see text). The trees and wood treatment are listed in Table 2. Overlapping decadal samples with mid-points no greater than one year apart were averaged. Single year data were averaged for the intervals AD 1510–1719 and AD 1790–1949.

*CL = cellulose method, DV = De Vries method

**Cellulose duplicates run for AD 1836, 1837 and 1853

†Cellulose treatment AD 1505 and 1515

TABLE 3

The conversion of the radiocarbon ages to a series of ranges of cal AD/BC (and BP) dates is determined by the AD/BC intercepts of the sample radiocarbon age $\pm \sqrt{(\text{sample } \sigma)^2 + (\text{curve } \sigma)^2}$ and the calibration curve. Intercepts of the radiocarbon age with the calibration curve are listed to the right. Sample σ is the standard error in the radiocarbon age.

The youngest decade of the calibration curve is AD 1940–1949 with a conventional radiocarbon age of 181 years BP. The curve has been extended to 1954 using data from Stuiver and Quay (1981). Nuclear bomb testing increased atmospheric ^{14}C substantially in 1955, resulting in the “vertical” portion of the Fig 1A calibration curve. Intercepts with this vertical portion yield the 1955*s of the table. In those instances where cal AD/BC ages indicate “negative” BP ages the BP age is given as 0* BP.

For sample sigmas and ranges larger or equal to 100 years the data were rounded to the nearest decade. When the gap between two successive ranges was less than 10 years, the two ranges were combined to a single one.

Illustrations from Stuiver and Pearson (1986) and Pearson and Stuiver (1986) are given below.

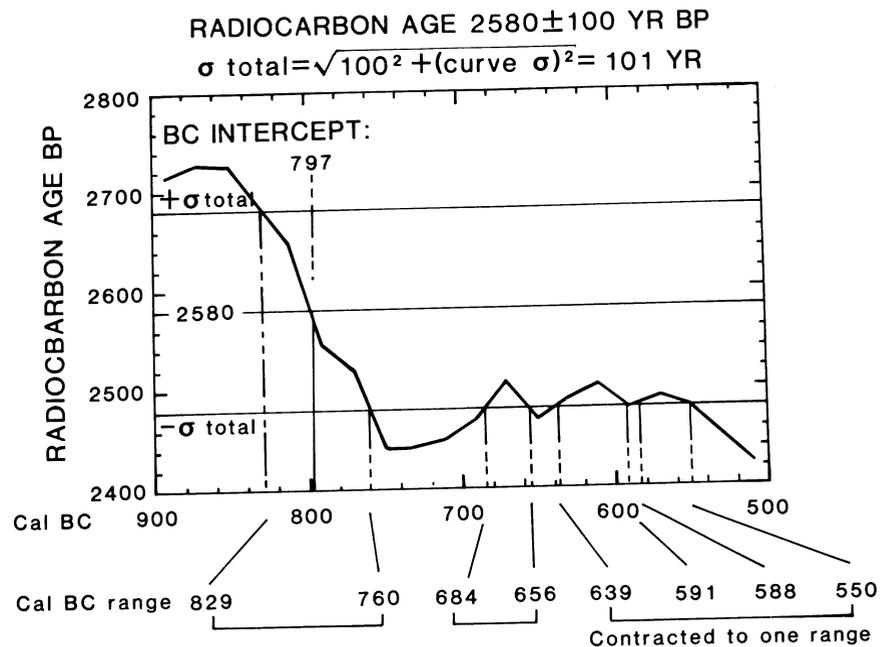

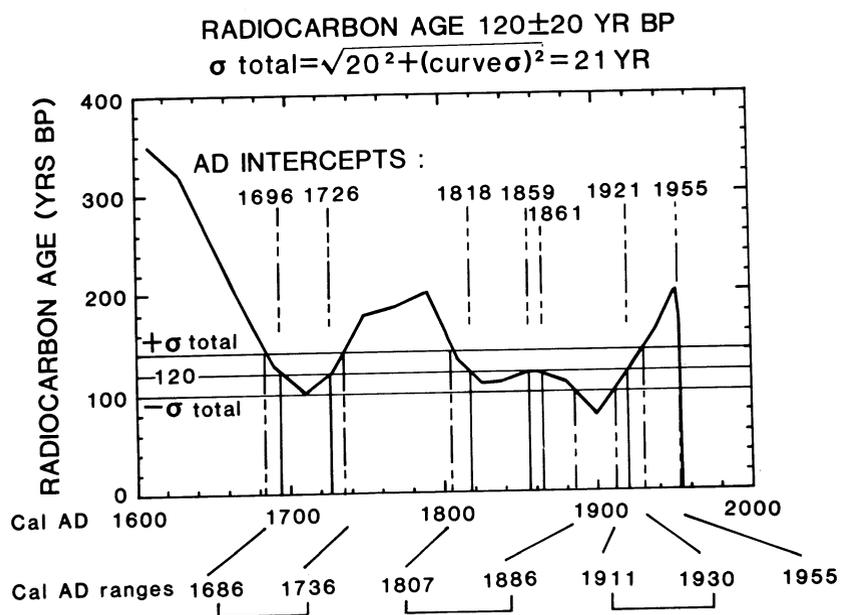

TABLE 3-A

RADIOCARBON AGE BP 80		CALIBRATED AGES:	
		cal AD 1897, 1908, 1955*	
		cal BP 53, 42, 0*	
Sample σ and cal AD(cal BP) ranges:			
$\sigma = 20$	1710-1717(240-233)	1883-1914(67-36)	
$\sigma = 40$	1693-1722(257-228)	1812-1922(138-28)	
$\sigma = 60$	1685-1730(265-220)	1808-1932(142-18)	
$\sigma = 80$	1677-1739(273-211)	1804-1939(146-11)	
$\sigma = 100$	1671-1747(279-203)	1761-1770(189-180)	1800-1955*(150-0*)

$\sigma = 160$	>2500-2270(>4450-4220)	2258-2205(4207-4154)	
$\sigma = 200$	>2500-2200(>4450-4150)	2160-2142(4109-4091)	

RADIOCARBON AGE BP 3960 CALIBRATED AGE: cal BC 2473
cal BP 4422

Sample σ and cal BC(cal BP) ranges:

$\sigma = 20$	2491-2470(4440-4419)		
$\sigma = 40$	2494-2468(4443-4417)		
$\sigma = 60$	>2495-2464(>4444-4413)	2437-2436(4386-4385)	2418-2410(4367-4359)
$\sigma = 80$	>2495-2400(>4444-4349)	2379-2353(4328-4302)	
$\sigma = 100$	>2500-2350(>4450-4300)		
$\sigma = 120$	>2500-2310(>4450-4260)		
$\sigma = 160$	>2500-2270(>4450-4220)	2252-2231(4201-4180)	
$\sigma = 200$	>2500-2200(>4450-4150)	2151-2145(4100-4094)	

Table 3-FFF

RADIOCARBON AGE BP 3980 CALIBRATED AGES: cal BC 2489, 2482, 2475
cal BP 4438, 4431, 4424

Sample σ and cal BC(cal BP) ranges:

$\sigma = 20$	2494-2472(4443-4421)		
$\sigma = 40$	>2495-2470(>4444-4419)		
$\sigma = 60$	>2495-2468(>4444-4417)		
$\sigma = 80$	>2495-2465(>4444-4414)	2418-2411(4367-4360)	
$\sigma = 100$	>2495-2400(>4444-4349)	2379-2353(4328-4302)	
$\sigma = 120$	>2500-2350(>4450-4300)		
$\sigma = 160$	>2500-2290(>4450-4240)	2247-2235(4196-4184)	
$\sigma = 200$	>2500-2270(>4450-4220)	2258-2205(4207-4154)	

RADIOCARBON AGE BP 4000 CALIBRATED AGE: cal BC 2492
cal BP 4441

Sample σ and cal BC(cal BP) ranges:

$\sigma = 20$	>2495-2474(>4444-4423)		
$\sigma = 40$	>2495-2472(>4444-4421)		
$\sigma = 60$	>2495-2470(>4444-4419)		
$\sigma = 80$	>2495-2468(>4444-4417)		
$\sigma = 100$	>2495-2465(>4444-4414)	2418-2411(4367-4360)	
$\sigma = 120$	>2495-2400(>4444-4349)	2379-2353(4328-4302)	
$\sigma = 160$	>2500-2310(>4450-4260)		
$\sigma = 200$	>2500-2270(>4450-4220)	2252-2231(4201-4180)	

RADIOCARBON AGE BP 4020 CALIBRATED AGE: cal BC 2496
cal BP 4445

Sample σ and cal BC(cal BP) ranges:

$\sigma = 20$	>2495-2490(>4444-4439)	2478-2476(4427-4425)	
$\sigma = 40$	>2495-2474(>4444-4423)		
$\sigma = 60$	>2495-2472(>4444-4421)		
$\sigma = 80$	>2495-2470(>4444-4419)		
$\sigma = 100$	>2495-2468(>4444-4417)		
$\sigma = 120$	>2495-2465(>4444-4414)	2418-2412(4367-4361)	
$\sigma = 160$	>2500-2350(>4450-4300)		
$\sigma = 200$	>2500-2290(>4450-4240)	2247-2235(4196-4184)
