

Acknowledgements

We thank the Stanley Foundation Neuropathology Consortium (M. Knable, F. Torrey, M. Webster and R. Yolken) for providing tissue used in this study. The technical assistance of Samantha Sachsenmaier and Umar Yazdani, and the editorial expertise of Laura Miller are greatly appreciated. The National Institute of Mental Health (MH59145), the Veterans Administration, the Zigenbein Memorial Fund, and the Theodore and Vada Stanley Foundation financially supported this work.

Psychosis – the price *Homo sapiens* pays for language

Tim Crow

Age- and sex-dependent uniformity across populations of the psychotic continuum reflects ontogeny of the *cerebral torque*. This *sapiens*-specific evolutionary innovation identified four compartments of association cortex as the language circuit: perceived speech > meaning > thought > speech production. Symptoms (due to directional asynchronies of callosal myelination) represent ‘leakages’ – negative anterior, positive posterior, linguistic to left, affective to right. The speciation event occurred 160KYA in the Y copy (*PCDHX*) of the *ProtocadherinXY* homologous gene pair with subsequent sequence change in *PCDHX*. Thus, language, *H. sapiens* & predisposition to psychosis resulted from a single chance event in a male, selected by females.
